Outcomes after cardiac arrest depend on the severity of global brain injury resulting from the ongoing injury due to gaps between brain energy supply and demand (secondary brain injury). Our overarching goal is to improve outcomes of individuals who experience refractory seizures after cardiac arrest via an open-label trial using Vigabatrin. The goal of this study is to demonstrate that vigabatrin can be absorbed when given in the post-cardiac arrest period.

This project is a collaboration between Egyptology researchers from the Joukowsky Institute at Brown University and medical imaging researchers at Rhode Island Hospital, to utilize diagnostic imaging techniques to confirm the identity of an unprovenanced 2000-year-old ibis mummy found at an archaeological site in Egypt. This unique application of imaging technology to archaeology research was sought because removing the wrapping from the mummy by hand would have risked damage to the delicate artifact. The study was used to confirm the presence of the mummified ibis inside the wrappings. Brown Digital Repository. Brown University Library. 2017; Project Data DOI: <https://doi.org/10.7301/Z0PZ56R5>
